An interactive terminal emulator is a software application which allows a user to enter keyboard input and view the output on-screen, often using the aforementioned chat window interface. An interactive terminal is a specific kind of emulator: it is an emulator that also communicates with the user by transmitting keyboard input and other information such as text and colors. Other examples of this are the DOS interfaces of early personal computers, the MS-DOS command prompt, or the GNU screen (since version 1.4). A terminal emulator can display the output of programs, such as different system messages, or text the user has typed into the application. This can also be extended to display images (created with a graphics editor), music (created in an audio editor), and arbitrary files and directories. A terminal emulator may be single-tasking or multi-tasking, and may be "windowless" or "window-based". The latter is the most common; it may present a thin rectangle ("window") filled by the text it is displaying. A terminal emulator may also have hidden layers or panels. The term terminal emulator is commonly used when referring to a program that can be used to manage terminals of a computer. Some terminal emulators can execute multiple processes on multiple virtual terminals simultaneously, while others can run a process on a single virtual terminal and provide multiple virtual terminals. The reason is that it is not easily understood why one should install a server in the first place. Why is it required and why does it bring with it an additional configuration burden for the developer/system administrator? It comes down to the fact that how information is transferred among networks and vice versa, is the main part that accounts for the amount of effort that needs to be placed into such a process. This tutorial will dive into the basics of how you can use Ansible to automate a basic software deployment using VirtualBox via a pre-installed VM. Software deployment can be done through several different means, like manual installation or deployment over some type of network (SOAP web services, centralized server, etc.). Ansible makes it so much easier to have a computer do what a user typed in an SSH command line. It allows for tasks to be defined and run over time, all through the use of scripts. Perhaps the main appeal of Ansible is that it is meant to be used to automate and script almost any type of software deployment. The fact that it can be used for small user-desktop automation is perhaps its biggest strength. Perhaps
